1 Introduction

TODO: Is halt die frage ob ma den anfang einfach so schreiben, war ja eigentlich net ganz so xD

Mobile apps are utilized for virtually all aspects of daily life in the modern world. So after we noticed that there is no application that allows the efficient planning of campaigns like the "Sternsinger-Aktion" we asked ourselves why, and furthermore, how hard it is to create an App with intuitive usability with the main purpose of simplifying the process of managing such a campaign and gaining a general overview of the progress made by the groups.

The app needs to comply with specific criteria we defined in cooperation with Prof. DI Robert Müllerferli. He is the main organizer of the campaign in the parish of Lieboch and helped us to work out the key aspects our project should implement. In the finished product, every user should be able to scan a QR-Code, through which the area of this group gets assigned to the device. These areas must be dynamically adjustable, so an admin can coordinate the workload of each area more efficiently. The areas also need to be clearly visible by an outline which gets drawn through "Border" addresses. These border addresses get calculated by an algorithm implemented by us. It should be visible at a glance if there is an "specification", which can be assigned by admins, set for an address. This should be realized through the use of different icons instead of the default icon. Apart from the app itself, we also implemented a web-portal through which administrators can manage and supervise the campaign.

TODO: vielleicht noch was rein bezüglich der borders und dann unten nurmehr drauf referenzieren?

The research part of this thesis will be dedicated to how components should act and look, so that new users can use this tool without requiring a long "onboarding" phase. It should feel familiar to interact with elements and the borders of what users can and can not do need to be clearly defined. Because our application also needs a reliable data source to guarantee the consistency and accuracy of marked addresses, we researched ways to keep our database up-to-date, without the need of much manual intervention. After defining the project requirements, we noticed that we need to calculate which addresses are border addresses. So we decided to take a look into different algorithms for this task and compare them concerning their efficiency, decide on one of them and implement it.

This thesis contains an in-depth description of our thought and development process, as well as any other steps we took to achieve our goal of a functional mobile application that can be used by volunteers in course of the "Sternsinger-Aktion 2025" taking place in the parish of Lieboch.

1.1 Team

Backend

2 Technologies

Development would not have been possible without making use of many tools, frameworks and environments. In this chapter each tool used in the creation of our software will be described briefly.

2.1 LaTeX

Hier kommt eine Beschreibung zu Latex hin

2.2 Frontend

2.2.1 Dart

Dart is a programming language initially designed for web development, with the goal, of replacing JavaScript, in mind. Today it gets used in a variety of software products, mainly because of the flutter framework. It can be compiled for many platforms and architectures (ARM, x64, RISC-V, JavaScript or WebAssembly) and is loved for its combination of High-Level Features, with practical language features like Garbage collection and optional Type annotation. It was developed by Google and is now an open-source project.

(Flutter for Beginners, n.d.)

2.2.2 Flutter

Flutter is an Open-Source software development framework. It allows programmers to compile their application for different platforms including Web, macOS, IOS as well as Windows and any type of Linux-based systems, all from one code-base, written in Dart. This allows for more efficient and faster cross-platform development. Another benefit of Google's toolkit are the highly customizable predefined UI components. Developers can mix and match these components however needed which makes them an applicable choice.

We chose flutter mainly for these reasons, but also because of our previous experience with Java to which Dart is quite similar. Through it, we were able to get started quickly, learn what we need along the way. Having a design through the components was also very helpful and saved us some time.

("flutter/README.md at master · flutter/flutter", 2025) (Dagne, 2019)

2.3 Backend

2.3.1 Java Spring

2.7 Deployment

2.7.1 Docker

2.7.2 Uberspace

2.7.3 Webmin

3 Research Questions

3.1 Leon Edlinger

3.2 Paul Gigler

3.3 Andreas Weissl

4 Spring Framework

The backend leverages the **Spring Framework**, a comprehensive framework for enterprise Java development. This section explores its key components and advantages.

4.1 Spring Boot

Spring Boot simplifies configuration and deployment with embedded servers and opinionated setups. This reduces boilerplate code and accelerates development.

4.2 Spring Data JPA

Spring Data JPA provides abstractions for database interactions, streamlining CRUD operations and custom query creation.

4.3 Lombok

Lombok reduces boilerplate code by generating getters, setters, and other methods at compile time, improving code readability and maintainability.

4.4 Advantages

Using Spring enhances productivity, reduces setup complexity, and ensures scalability, making it ideal for this project.

5 Area Borders

The area borders feature addresses the research question by implementing computational geometry algorithms for precise geographical boundary calculations.

5.1 Purpose of Area Borders in the App

Accurate area borders are essential for defining regions based on user input, supporting the app's mapping functionality.

5.2 Overview of the Convex Hull Algorithm

The convex hull algorithm identifies the smallest convex polygon enclosing a set of points, making it a suitable choice for this project.

5.3 Use Cases of the Convex Hull in Industry

Applications of convex hulls in mapping, computer graphics, and robotics highlight their importance in solving real-world problems.

5.4 Alternate Methods for Area Border Calculation

Alternative methods like Voronoi diagrams and alpha shapes were considered but found less suitable due to complexity or computational demands.

5.5 Rationale for Choosing the Convex Hull Method

The convex hull algorithm offers a balance of simplicity, efficiency, and accuracy, aligning with the project's requirements.

5.6 Integration of the Algorithm into the Backend

The algorithm is implemented in the service layer, ensuring smooth integration with other backend components.

5.7 Challenges and Adjustments

Challenges included handling edge cases like collinear points, which were resolved through specific algorithm adjustments.

6 Structure of the Backend

The backend follows a layered architecture to promote separation of concerns, scalability, and maintainability. This section outlines the roles of each layer.

6.1 Controller Layer

The controller layer acts as the interface for incoming HTTP requests, delegating them to appropriate service methods.

6.2 Service Layer

The service layer contains business logic, validating data and coordinating interactions between controllers and repositories.

6.3 Repository Layer

Repositories abstract database operations, allowing the backend to interact with the database without explicit SQL queries.

6.4 Persistence Layer (Entity Classes)

Entity classes define the data model and its mapping to the relational database, ensuring a consistent schema.

6.5 Applied Design Principles (DTOs)

Data Transfer Objects (DTOs) enhance encapsulation and optimize data transfer between layers and external clients.

7 Defining usability

7.1 Why it is important

7.2 Fundamental concepts of usability

7.3 Challenges in designing for a broad user spectrum

8 Usability in context of maps

8.1 Basic Analysis of the Google Maps interface

8.2 Identifying Flaws in Googles Design

8.3 How could specific user groups struggle with this design

9 Adaptive algorithms and real-time data integration

9.1 Theoretical Framework

9.1.1 Traditional Methods for Address Database Management

9.1.2 Adaptive Algorithms: Concepts and Applications

9.1.3 Real-Time Data Integration Frameworks

9.2 Technical Framework

9.2.1 Data Sources

9.2.1.1 GPS Data

9.2.1.2 External APIs

9.2.1.3 User Inputs

9.2.2 Adaptive Algorithms

9.2.2.1 Fuzzy Matching

9.2.2.2 Machine Learning Model

9.2.2.3 Rule-Based Filters

9.2.2.4 Dynamic Duplicate Resolution

9.2.2.5 Real-Time Address Normalization

9.2.3 Evaluation Metrics

9.2.3.1 Accuracy

9.2.3.2 Latency

10 Traditional Methods for Address Database Management

11 Adaptive Algorithms: Concepts and Applications

12 Real-Time Data Integration Frameworks

13 Implementation of the Backend

The backend implementation combines theoretical concepts with practical solutions to ensure functionality and scalability.

13.1 Config of Spring Boot (application.properties)

The `application.properties` file configures essential settings, including database connections, logging, and server parameters.

13.2 Entity Classes (Structure/Purpose)

Entity classes define the application's data model, using annotations to map fields to database tables.

13.3 JPA-Repositories (DB Access and CRUD Operations)

Repositories simplify database access by providing methods for CRUD operations and enabling custom queries.

13.4 Service Classes

Service classes encapsulate business logic, coordinating data flow between controllers and repositories.

13.5 Rest Controller (API Endpoints and their Functions)

REST controllers define API endpoints, processing requests and returning responses to ensure seamless interaction with the frontend.

14 GraphHopper Setup

14.1 Why use GraphHopper?

14.2 Configuration

14.3 Local hosting

15 Working out the Wireframes

15.1 Map View

15.2 List View

15.3 Possible improvements for future versions

16 Functional implementation behind the application

16.1 Address-Provider

16.2 HTTP-Requests

16.3 Implementation of the Flutter Map Component

17 The app in use

17.1 Introducing new users

17.2 The app in operation

17.3 User Feedback

18 Implementation Admin Panel

The Admin Panel is a centralized administrative dashboard to efficiently manage all addresses within a single environment. It is used to plan for future "Sternsinger" events, ensuring that every address that needs to be visited is covered and that all addresses are efficiently distributed among participating groups. Additionally, it enables the assignment of areas containing addresses a group needs to visit. This zoning feature ensures that each group is responsible for visiting only the addresses within their assigned area.

With the tool, administrators can perform CRUD (Create, Read, Update, Delete) operations on addresses, streets, and areas. These features make it easy to quickly address issues and make changes to the areas that participants need to visit. For example, if a new street is added to the neighborhood, the administrator can update the system to include this street and assign it to the appropriate area. Similarly, if a group drops out, the administrator can quickly reassign the addresses that have not yet been visited to other groups. This ensures that the data remains up-to-date and allows for quick reactions to special cases, helping with the planning and execution of "Sternsinger" events.

This chapter will outline the implementation of the Admin Panel and describe the different components, functionalities, and widgets of this tool. Additionally, it will provide information on how to use it.

18.1 Navigation

To navigate between pages, a sidebar on the left is used, which can be toggled with a button in the top-left corner of the screen. It shows a list of all pages, allowing users to switch between them with a click.

The navigation is implemented in the file `AdminNavigation`. It contains a list of pages with titles. These titles are displayed at the top of the screen above the corresponding page. To keep track of the currently selected page, an internal state (`indexState`) is used. Whenever a page is selected in the sidebar, the `indexState` is updated, and the corresponding page is displayed. This widget is the main component. It makes sure that all pages are properly displayed.

Abb. 1: Navigation in Admin-Panel

18.2 AddressPage

The first page, the `AddressPage`, displays an interface to create, update, and delete address data. It uses a form with various input fields (e.g., street, house number, coordinates, special features) and a map or database view to visualize and select addresses. The page is divided into two parts:

- On the right side, all addresses are shown either in the `AdminMapComponent` (18.4.1) or the `DatabaseViewComponent` (18.4.2). These two components display the same addresses but in different ways, to give the administrator the choice of how they want to view the addresses.
- On the left side of the page are `InputFields` (18.6.1), which are used to enter new information about a new address or edit an existing one.

Overlaying the `AdminMapComponent`, there are:

- A field to filter the addresses displayed.
- A button with a dropdown menu to select and edit a street.
- A switch to toggle between the `AdminMapComponent` and the `DatabaseViewComponent`.
- An information box in the bottom left corner to display `Notifications` (18.2.5.1) about the completed operations.
- A field in the bottom right corner to display the coordinates of the mouse pointer on the map.

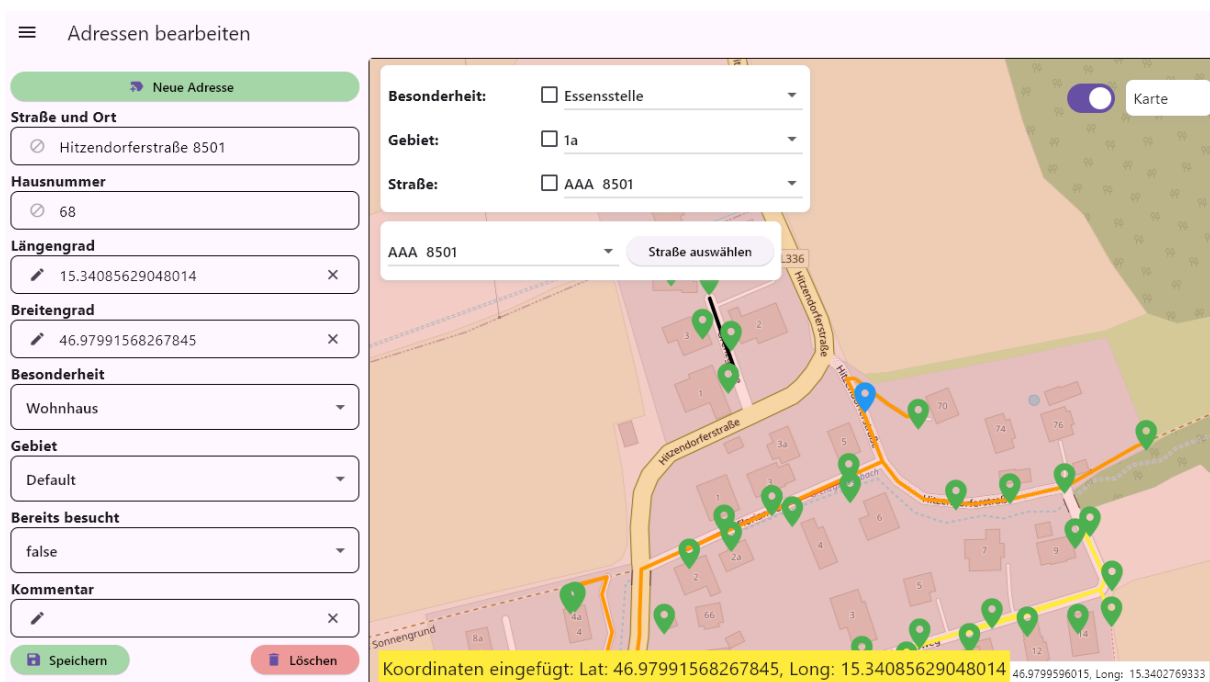

Abb. 2: AddressPage

18.2.1 Add Address

To add a new address, the button "Neue Adresse" is pressed. A single click on the map does the same thing, however it automatically fills in the coordinates of the location where the mouse was clicked. This triggers the `onClickNewAddress` method, which performs several key operations:

- All `InputFields` are cleared.
- The boolean variable `isNewAddress` is set to `true`, indicating that a new address is being created.

The cleared fields can then be filled with the new information. When the "Speichern" button is pressed, the `saveAddress` method is called. This method performs several validation checks which can be seen in 18.2.4. If the address is valid, the `AdminAddressProvider` is called to add it to the database. If the operation was successful, a `Notification` is displayed and the newly added address appears on the map.

18.2.2 Edit Address

Existing addresses can be edited by selecting an address in either the `AdminMapComponent` or the `DatabaseViewComponent`. The selection fills the `InputFields` with the information of the selected address, and in this case, the boolean variable `isNewAddress` is set to `false` to indicate that an existing address is being updated.

The admin can then edit the information and press the "Speichern" button. This triggers the `saveAddress` method, which performs the same validation checks as when adding a new address. The `AdminAddressProvider` updates the selected addresses in the database, and the `Notification` is shown.

18.2.3 Delete Address

After selecting an address, the admin can press the "Löschen" button to delete it. This triggers the `deleteAddress` method, which calls the `AdminAddressProvider` to delete the selected addresses and displays the `Notification`.

The method also triggers the `showDeleteDialog` method, which displays a `AlertDialog` to confirm the action and prevent accidental deletions.

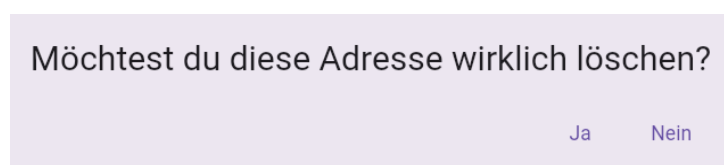

Abb. 3: Dialog to confirm deletion

18.2.4 Validation

Validation is the process of checking that data meets specific criteria before it is accepted and added. It is crucial to ensure that the data entered is correct, consistent, and meets the required standards to maintain data integrity and reliability. (Contributors to Wikimedia projects, 2025)

18.2.4.1 isDuplicateAddress

To determine whether an edited or newly added address already exists, All addresses are compared with the new address. It is called in the `saveAddress` method. If it already exists, the method returns `true`, otherwise `false`. A duplicate address is identified by the following criteria:

- street name
- postal code
- house number

```
bool isDuplicateAddress(List<Address> existingAddresses, Address
newAddress) {
    return existingAddresses.any((existing) =>
        existing.street.name == newAddress.street.name &&
        existing.street.postalCode == newAddress.street.postalCode &&
        existing.houseNumber == newAddress.houseNumber
    );
}
```

Quellcode 1: isDuplicateAddress method

18.2.4.2 InputField filled Validation

To make sure that all `InputFields` are filled, the `validateAddressFields` is called in the `saveAddress` (18.2.1) method. This method needs an `Address`. So first an new `Address` is made and passed to `validateAddressFields`. It checks if all fields are filled and returns `true` if they are, otherwise `false`.

```
bool validateAddressFields(Address address) {
    if (address.street.name.isEmpty) {
        showNotification("Strasse fehlt", () => showAddAddressNotification =
            true);
    } else if (address.houseNumber.isEmpty) {
        showNotification("Hausnummer fehlt", () => showAddAddressNotification
            = true);
    } else if (address.specialFeature.text.isEmpty) {
        showNotification("Besonderheit fehlt", () =>
            showAddAddressNotification = true);
    }
}
```

```

    } else if (address.area.desc.isEmpty) {
        showNotification("Gebiet fehlt", () => showAddAddressNotification =
            true);
    } else if (address.latitude == 0.0 || address.longitude == 0.0) {
        showNotification("Koordinaten fehlen", () =>
            showAddAddressNotification = true);
    } else {return true;}
    return false;
}

```

Quellcode 2: InputFormatter in Inputfield

18.2.4.3 InputField Coordinates Validation

The `InputField` validates **latitude** and **longitude** inputs to ensure their correctness. Validation is applied only when the `isCoordinateInput` parameter is set to true. If that is the case, then the `inputFormatter` is passed to the `textfield` to validate the input. This `inputFormatter` guarantees that only valid inputs are accepted, preventing incorrect entries. These are the three validators used in the `InputField`:

- A `FilteringTextInputFormatter` with a regular expression is used to restrict the input to digits, decimal points, and an optional minus sign at the beginning.

`r'^-?[0-9.]*`

Abb. 4: Regular expression for input validation

- A `TextInputFormatter` prevents multiple decimal points in a single number. If a user attempts to insert a second decimal point, the input is automatically rejected.
- The last `TextInputFormatter` ensures the number of digits before the decimal point is limited to a maximum of 3. Additionally, the value before the decimal point must not exceed 180.

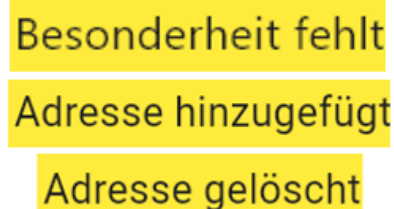

18.2.5 Additional Functionalities

This section highlights various functionalities implemented to improve the overall usability of the application. These additions are designed to support administrative tasks and ensure a seamless user experience.

18.2.5.1 Notification

To inform the administrator about the success or failure of an operation, a `Notification` is displayed on the bottom left, overlaying the `AdminMapComponent`. This notification appears when:

- An address is added, edited, or deleted.
- Validation fails.
- Coordinates are selected on the `AdminMapComponent` (18.4.1.3).

Adresse gelöscht

Abb. 5: Notification examples

To display this notification, the `showNotification` method is called. This method sets the `notificationVisible` variable to `true` and starts a `Timer` to turn it set it back to `false` three seconds later, so it goes away in a short time. This method accepts a message as a parameter, which is saved in the `notificationText` variable.

```
void showNotification(String message) {
    setState(() {
        notificationText = message;
        notificationVisible = true;
    });
    Timer(Duration(seconds: 5), () {
        setState(() {
            notificationVisible = false;
        });
    });
}
```

Quellcode 3: showNotification method

When the `notificationVisible` variable is set to `true`, the UI-component which shows the notification is rendered.

```
Positioned(
  left: 10,
  bottom: 10,
  child: (notificationVisible)
    ? Container(
      padding: EdgeInsets.all(4),
      color: Colors.yellow,
      child: Text(
        notificationText,
        style: TextStyle(fontSize: 20),
      ),
    )
    : Container(),
),
```

Quellcode 4: Notification in AddressPage

18.2.6 Edit multiple addresses

To make it easier to edit multiple addresses at once, the CTRL-Button on the keyboard is listened to. When the CTRL-Button is pressed, the `isCtrlPressed` variable is set to `true`. This variable is passed to the `DatabaseViewComponent` and the `AdminMapComponent`, to inform them that multiple addresses want to be selected. The components can use the, as a parameter given, `markerSelected` function to set the selected addresses in the `AddressPage`. The `saveAddress` method is called to save multiple addresses.

To listen to the CTRL-Button, the predefined `RawKeyboardListener` is used. This widget sets the `isCtrlPressed` variable to `true` when the CTRL-Button is pressed and to `false` when it is released. To make sure that repeatedly pressing the CTRL-Button, which happens if the button is pressed and held, does not interfere with the `isCtrlPressed` variable, the condition `event.repeat == false` is used.

```
RawKeyboardListener(
  autofocus: true,
  focusNode: FocusNode(),
  onKey: (event) {
    if ((event.isKeyPressed(LogicalKeyboardKey.controlLeft) ||
      event.isKeyPressed(LogicalKeyboardKey.control) ||
      event.isKeyPressed(LogicalKeyboardKey.controlRight)) &&
      event.repeat == false) {
      setState(() {
        isCtrlPressed = true;
      });
    }
  },
)
```

```

    });
  } else if (event is RawKeyUpEvent && event.logicalKey ==
    LogicalKeyboardKey.controlLeft) {
    setState(() {
      isCtrlPressed = false;
    });
  }
},
),

```

Quellcode 5: RawKeyboardListener in AddressPage

The `markerSelected` method also updates the `InputField` for the house number by listing the house numbers of the selected addresses in the controller.

```

controllers["houseNumber"]?.text = selectedAddresses
  .map((address) => address.houseNumber)
  .toList()
  .join(', ');

```

Quellcode 6: Listed house numbers for multiple selected addresses

The `InputField` looks like this:

Abb. 6: House numbers of multiple selected addresses

The selected addresses are saved in the `selectedAddresses` variable in the `AddressPage`. If multiple addresses are selected, certain `InputFields` such as house numbers, coordinates, or comments will be disabled because changing them for all selected addresses would not make sense. This can be achieved by setting the `editable` parameter of these `InputFields` to `selectedAddresses.length <= 1`, so that they are only editable when a single address is selected.

18.2.7 Edit all Addresses from a Street

All addresses from a street can be edited at once. This is almost the same as editing multiple addresses (18.2.6), but instead of selecting the addresses by clicking on them, a street is selected. When a street is selected, all its addresses are selected. A street can be selected in two ways:

18.2.7.1 Select Street via AdminMapComponent

Every click on the `AdminMapComponent` is checked if it is near a street. Because there is no predefined method to check if a point is on a street, the `isPointNearPolyline` method was implemented. This

method checks if the click was on the street. More information about this method can be found in the `AdminMapComponent` section 18.4.1.

18.2.7.2 Select Street via Button

This was implemented because we encountered a problem where it was not possible to click on a street on some devices. To ensure that this feature is usable on all devices, a dropdown button to choose a street and a button to select it were implemented.

Abb. 7: Button to select a street

18.2.8 Edit Odd / Even Streets

One requirement was that addresses from one street could be automatically added to two areas based on whether the house number is even or odd. This is because it is common for all addresses with even house numbers to be on one side of the street and those with odd house numbers on the other side. This way, it is easier to assign the street sides to different areas, so that "Sternsinger" participants don't have to cross the street so often.

To make this possible, the administrator has to select a street in the `AdminMapComponent` (18.4.1.1), then a blue button beneath the `InputFields` appears.

Abb. 8: Button to split street

After pressing this button, a dialog appears, where the administrator can select the areas for the addresses with even and odd house numbers.

Abb. 9: Dialog to split street

The "Speichern" button triggers the `AdminAddressProvider` and shows a `Notification` (18.2.5.1) if the operation was successful or not. After that, the dialog is closed.

```
int resultCode = await
    addressProvider.putAddressesOddEven(selectedAddresses.first.street.name,
    selectedAddresses.first.street.postalCode, selectedAreaEven,
    selectedAreaOdd);
if (resultCode == 200) {
    showNotification("Adressen gespeichert", () =>
        showAddressSavedNotification = true);
} else {
    showNotification("Fehler beim Speichern", () => showAddAddressNotification
        = true);
}
if (!context.mounted) return;
Navigator.of(context).pop();
```

Quellcode 7: onPressed save button in splitStreetDialog

18.2.9 Filter

With the Filter field, the administrator can filter the addresses displayed. It contains three dropdown menus to set the filter criteria, with one checkbox for each to toggle them. These filters can be combined as desired.

Besonderheit:	<input type="checkbox"/> Besuch nicht gewünscht	▼
Gebiet:	<input type="checkbox"/> 1a	▼
Straße:	<input checked="" type="checkbox"/> Amselgasse 8501	▼

Abb. 10: Filter field in AddressPage

The filter is passed and applied to the `AdminMapComponent` and the `DatabaseViewComponent`. The criteria and their enabled/disabled state are managed by the following variables in the `AddressPage` class.

```
bool specialFeatureFilter = false;
bool areaFilter = false;
bool streetFilter = false;

String selectedStreetFilter = "";
String selectedSpecialFeatureFilter = "";
String selectedAreaFilter = "";
```

Quellcode 8: Filter variables in AddressPage

This is an example of how a `FilterRow` is defined in the `AddressPage` class (18.6.2):

```
FilterRow(
    label: "Besonderheit:",
    tooltipMessage: "Besonderheitsfilter aktivieren/deaktivieren",
    filterValue: specialFeatureFilter,
    onFilterChanged: (bool? newValue) {
```

```

        setState(() => specialFeatureFilter = newValue ?? false);
    },
    selectedValue: selectedSpecialFeatureFilter,
    items: specialFeatureTextList,
    onDropDownChanged: (String? newValue) {
        setState(() => selectedSpecialFeatureFilter = newValue ?? "");
    },
),

```

Quellcode 9: FilterRow in AddressPage

18.3 ListEditPage

The `ListEditPage` is used to manage **streets**, **special features**, and **areas**. It allows the administrator to add, edit, and delete these entities. The page is divided into two parts. On the right side, all entities are displayed in a table and can be selected. On the left, there is a dropdown menu for selecting between the three options. The information of the selected item is shown in `InputFields` on the this side, where the information can be edited, saved or deleted using the "Speichern" or the "Löschen" button.

Abb. 11: ListEditPage

18.3.1 QR-Code Visualization for Areas

To make it easier for users of the user application to get information about their area, a QR-Code is generated for every area, which can be scanned to get all information. The QR-Code contains the name of the area. The currently selected area is saved in the `selectedItem` variable.

Abb. 12: QR-Code for area

To display the QR-Code, the `QrImageView` Widget is used.

```
QrImageView(
  data: selectedItem,
  size: 300,
  padding: const EdgeInsets.all(16.0),
  gapless: false,
),
```

Quellcode 10: QrCode Generation in ListEditPage

18.3.2 QR-Code-PDF Download

A PDF with all QR-Codes for all areas can be downloaded, making it easier to distribute the information to users. The PDF is generated with the `savePDF` method of the `PDFSaver` class.

A QR-Code is generated with the `generateQRCode` method in the `ListEditPage` class. This method takes a string as the parameter and converts this string to a QR-Code using the predefined `QrPainter`, which helps with painting a QR-Code (“QrPainter class - qr_flutter library - Dart API”, 2025). The method then generates an image of the QR code with this class, converts this into byte data in PNG format, and finally transforms the byte data into a list of bytes (`Uint8List`) that can be used to display the QR-code in the pdf.

The `savePdf` method generates a PDF document containing QR-codes for all areas. It uses the predefined `pdf` package, imported as `pw`, to create and manage the PDF (“pdf | Dart package”, 2025). The function starts by initializing a new PDF using the `pw.Document()` class and an empty list to store the generated QR codes. It then iterates over a list of areas, generating a QR code for each area’s description using the `generateQRCode` method and adding it to the list.

After that, a page is added to the PDF document using the `pw.MultiPage` widget, which includes a title and every description of all areas with their corresponding QR-codes. After building the page content, the PDF data is saved to a variable by calling `pdf.save()`. Finally, the `PdfSaver.savePdf` method is called with the data to save it to a PDF named "Gebiete.pdf".

TODO: QR-Code PDF Download Foto einfügen

18.4 Components

18.4.1 AdminMapComponent

With this component, the addresses can be displayed on a geographic map. The map used is the OpenStreetMap which is free to use for everyone. Even though the Admin Panel is not used commercially, OpenStreetMap's attribution rules are followed. The map shows the required copyright notice "© OpenStreetMap contributors" in the bottom-left corner. The word "OpenStreetMap" is clickable and links directly to <https://www.openstreetmap.org/copyright>, opening the official license page in a new tab. This meets OpenStreetMap's license requirements by clearly acknowledging the data source and linking to their terms. ("Urheberrecht und Lizenz", 2025)

Abb. 13: OpenStreetMap attribution

18.4.1.1 Select Street

To select a street, the `isPointNearPolyline` method was implemented. This method checks if the click was on a street. As parameters, it takes the coordinates of the click as a `LatLng` object and a street as a list of `LatLngs`. After each click on the map, a loop is triggered that calls the `isPointNearPolyline` method for every street, passing the click coordinates during each iteration.

The `isPointNearPolyline` uses another loop, which iterates over all points of the street. Because the street is represented as a list of `LatLngs`, every two points are connected to form a line. Every iteration of the loop a helper method `isNear` is called, which calculates the distance between the click and the currently iterated line segment.

```
bool isPointNearPolyline(LatLng point, List<LatLng> polylinePoints) {
    const double tolerance = 0.00005;
    for (int i = 0; i < polylinePoints.length - 1; i++) {
        if (_isNear(point, polylinePoints[i], polylinePoints[i + 1], tolerance)) {
            return true;
        }
    }
    return false;
}
```

Quellcode 11: isPointNearPolyline method

The `isNear` method takes the click point, the two points for the line and the tolerance. If the distance is smaller than the predefined tolerance, the method returns `true`, indicating that the click was on the street.

```
bool _isNear(LatLng p, LatLng a, LatLng b, double tolerance) {
    double dx = b.latitude - a.latitude;
    double dy = b.longitude - a.longitude;
    double t = ((p.latitude - a.latitude) * dx + (p.longitude - a.longitude) *
        dy) / (dx * dx + dy * dy);
    t = t.clamp(0, 1);
    double cx = a.latitude + t * dx;
    double cy = a.longitude + t * dy;
    return (p.latitude - cx).abs() + (p.longitude - cy).abs() <= tolerance;
}
```

Quellcode 12: isNear method

18.4.1.2 onClickNewAddress

18.4.1.3 Select Coordinates on Map

18.4.2 DatabaseViewComponent

To display the addresses in a table, this component is used. As parameters it takes the `selectedAddresses`, the filter variables as well as the `isCtrlPressed` variable from the `AddressPage`, which is used to track if multiple addresses want to be selected. The `selectedAddresses` are displayed in the table and can be selected by clicking on them.

On the top are two fields

18.4.3 PDFSaver

The `PdfSaver` class provides a static method to save a PDF file from a byte array. The method `savePdf` takes a `Uint8List` of bytes and a `String` representing the file name as parameters. Depending on the platform, it saves the PDF file accordingly.

```
static Future<void> savePdf(Uint8List bytes, String fileName) async {
    if (kIsWeb) {
        final blob = html.Blob([bytes], 'application/pdf');
        final url = html.Url.createObjectUrlFromBlob(blob);
        final anchor = html.AnchorElement(href: url)
            ..target = 'blank'
            ..download = fileName
            ..click();
        html.Url.revokeObjectUrl(url);
    }
}
```

```

    } else {
      await FileSaver.instance.saveFile(
        name: fileName,
        bytes: bytes,
        ext: 'pdf',
        mimeType:MimeType.pdf,
      );
    }
  }
}

```

Quellcode 13: savePdf method in PDFSaver

18.4.4 AdminAddressProvider

This class serves as a bridge between the Admin Panel and the backend. It is responsible for all CRUD operations on addresses, streets, special features, and areas. It is used in the `AddressPage` and the `ListEditPage`. The `AdminAddressProvider` includes the `ChangeNotifier` mixin. A mixin is a way to reuse code across multiple classes, without using inheritance like in Java. (“Mixins”, 2025) The `ChangeNotifier` mixin is used to notify the UI when the data changes. (“ChangeNotifier class - foundation library - Dart API”, 2025) This is done by calling the `notifyListeners` method.

Here is a typical method in the `AdminAddressProvider` class. It contains these functionalities:

- `async` : enables non-blocking operations and ensures that the UI remains responsive while waiting for tasks like network requests to complete.
- `await http.get` : sends a GET request to the server to fetch all streets and waits for the response.
- `jsonDecode` : processes the JSON response from the server.
- `utf8.decode` : transforms the UTF-8 encoded response body into readable text.
- `map` : converts the decoded JSON to a list of `Street` objects.
- `sort` : sorts the list alphabetically.
- `notifyListeners` : notifies the listeners that the data has changed.
- `catch` : catches any errors that occur during the operation.

```

Future<void> fetchStreets() async {
  try {
    final response = await
      http.get(Uri.parse('$serverURL/$baseURL/admin/getAllStreets'));
    if (response.statusCode == 200) {

```

```

final List<dynamic> decodedJSON =
    jsonDecode(utf8.decode(response.bodyBytes));
streets = decodedJSON.map((json) => Street.fromJson(json)).toList();
streets.sort((a, b) => a.name.compareTo(b.name));
notifyListeners();
} else {
    throw Exception('Failed to load streets');
}
} catch (e) {
    print('Error fetching streets: $e');
}
}

```

Quellcode 14: typical method in AdminAddressProvider

18.4.5 CustomHttpClient

18.5 Models

18.5.1 AreaWithBorder

18.5.2 ScreenItem

18.6 Widgets

18.6.1 InputField

This widget defines a customizable input field. The `InputField` requires a label and a `TextEditingController` for managing the input. Optional parameters include a boolean `editable`, a list of `Strings` called `dropDownOptions` and a boolean `isCoordinateInput` to specify if the input should be numeric.

To display if the `InputField` is editable, icons are displayed on the left side of the field. If the field is not editable, the icon is a blocked symbol, and if it is editable, a pencil is displayed. When the `InputField` is editable and it is not a dropdown, a cross is displayed on the right side. When it is pressed, the content is cleared.

Abb. 14: InputField examples

If the `dropDownOptions` parameter is provided with a non-empty list of strings, the input field renders as a dropdown menu. The selected value is displayed, and users can choose from the provided options. The

dropdown value is automatically synced with the `TextEditingController`.

To guarantee valid inputs, the `InputField` uses an `inputFormatter` to validate the input. This formatter is only applied when the `isNumberInput` parameter is set to true. For further information about the validation, see 18.2.4.3.

18.6.2 FilterRow

This widget defines a reusable filter row. The `FilterRow` combines a label, a toggleable checkbox, and a dropdown menu to enable dynamic data filtering. It requires several parameters:

- `label` : A string for identifying the filter.
- `tooltipMessage` : A message to display when hovering over the checkbox.
- `filterValue` : A boolean to track the filter's active state.
- `items` : A list of strings for the dropdown options.
- `selectedValue` : Manages the selected dropdown value.
- `onFilterChanged` : A callback for updating the filter state.
- `onDropdownChanged` : A callback for updating the selected dropdown value.
